

# Analysis of Algorithms

## Hash Tables

Andres Mendez-Vazquez

September 24, 2020

# Outline

## 1 Basic Data Structures and Operations

- The Basics

## 2 Hash tables

- Concepts
- The Small and Large Universe of Keys
- Collisions and Chaining
- Analysis of hashing under Chaining
- The Successful and Unsuccessful Search

## 3 Hashing Methods

- Which Hash Function?
- The Division Method
- The Multiplication Method
- Clustering Analysis of Hashing Functions
  - First, Enforcing the Uniform Hash Distribution
  - Second, There is no Uniform Hash Distribution
- A Possible Solution, Universal Hashing
- Universal Hash Functions
- Example by a Posteriori Idea

## 4 Open Addressing

- Introduction
- Hashing Methods
- Linear Probing
- Linear Probing, Insertion and Deletion
  - Now, A Problem
- Quadratic Probing
- Double Hashing
- Analysis of Open Addressing

## 5 Exercises

# Outline

## 1 Basic Data Structures and Operations

# About Basic Data Structures

## Remark

It is quite interesting to notice that many data structures actually share similar operations!!!

Yes

If you think them as ADT

# About Basic Data Structures

## Remark

It is quite interesting to notice that many data structures actually share similar operations!!!

## Yes

If you think them as ADT

# Examples

## Search(S,k)

Example: Search in a BST

# Examples

## Insert(S,x)

Example: Insert in a linked list

# And Again

## Delete(S,x)

Example: Delete in a BST

# Basic data structures and operations.

## Therefore

This are basic structures, it is up to you to read about them.

- Chapter 10 Cormen's book

# Outline

## 1 Basic Data Structures and Operations

- The Basics

## 2 Hash tables

### ● Concepts

- The Small and Large Universe of Keys
- Collisions and Chaining
- Analysis of hashing under Chaining
- The Successful and Unsuccessful Search

## 5 Exercises

# Hash tables: Concepts

## Definition

- A hash table or hash map  $T$  is a data structure, most commonly an array, that uses a hash function to efficiently map certain identifiers of keys (e.g. person names) to associated values.

# Hash tables: Concepts

## Definition

- A hash table or hash map  $T$  is a data structure, most commonly an array, that uses a hash function to efficiently map certain identifiers of keys (e.g. person names) to associated values.

## Advantages

- They have the advantage of having a expected complexity of operations of  $O(1 + \alpha)$

▶ Still, be aware of  $\alpha$

# Hash tables: Concepts

## Definition

- A hash table or hash map  $T$  is a data structure, most commonly an array, that uses a hash function to efficiently map certain identifiers of keys (e.g. person names) to associated values.

## Advantages

- They have the advantage of having a expected complexity of operations of  $O(1 + \alpha)$ 
  - ▶ Still, be aware of  $\alpha$

However, if you have a large number of keys  $|U|$

- Then, it is impractical to store a table of the size of  $|U|$ .
- Thus, you can use a hash function  $h : U \rightarrow \{0, 1, \dots, m - 1\}$

## 5 Exercises

# When you have a small universe of keys, $U$

## Remarks

- It is not necessary to map the key values.
- Key values are direct addresses in the array.
- Direct implementation or Direct-address tables.

# When you have a small universe of keys, $U$

## Remarks

- It is not necessary to map the key values.
- Key values are direct addresses in the array.
- Direct implementation or Direct-address tables.

## Operations

- Direct-Address-Search( $T, k$ )
  - ▶ return  $T[k]$
- Direct-Address-Search( $T, x$ )
  - ▶  $T[x.key] = x$
- Direct-Address-Delete( $T, x$ )
  - ▶  $T[x.key] = NIL$

# When you have a small universe of keys, $U$

## Remarks

- It is not necessary to map the key values.
- Key values are direct addresses in the array.
- Direct implementation or Direct-address tables.

When you have a large universe of keys,  $U$

Then

Then, it is impractical to store a table of the size of  $|U|$ .

You can use a special function for mapping

$$h : U \rightarrow \{0, 1, \dots, m-1\} \quad (1)$$

Problem

With a large enough universe  $U$ , two keys can hash to the same value

- This is called a collision.

When you have a large universe of keys,  $U$

# Collisions

This is a problem

We might try to avoid this by using a suitable hash function  $h$ .

# Collisions

This is a problem

We might try to avoid this by using a suitable hash function  $h$ .

Idea

Make appear to be “random” enough to avoid collisions altogether (**Highly Improbable**) or to minimize the probability of them.

# Collisions

This is a problem

We might try to avoid this by using a suitable hash function  $h$ .

Idea

Make appear to be “random” enough to avoid collisions altogether (**Highly Improbable**) or to minimize the probability of them.

You still have the problem of collisions

Possible Solutions to the problem:

- Chaining
- Open Addressing

# Analysis of hashing with Chaining: Assumptions

## Assumptions

- We have a load factor  $\alpha = \frac{n}{m}$ , where  $m$  is the size of the hash table  $T$ , and  $n$  is the number of elements to store.
- Simple uniform hashing property:
  - ▶ This means that any of the  $m$  slots can be selected.
  - ▶ This means that if  $n = n_0 + n_1 + \dots + n_{m-1}$ , we have that  $E(n_j) = \alpha$ .

# Analysis of hashing with Chaining: Assumptions

## Assumptions

Therefore

We have two phenomena's

Second one

Therefore

We have two phenomena's

Second one

## For this, we have the following theorems

### Theorem 11.1

In a hash table in which collisions are resolved by chaining, an unsuccessful search takes average-case time  $\Theta(1 + \alpha)$ , under the assumption of simple uniform hashing.

### Theorem 11.2

In a hash table in which collisions are resolved by chaining, a successful search takes average-case time  $\Theta(1 + \alpha)$  under the assumption of simple uniform hashing.

## For this, we have the following theorems

### Theorem 11.1

In a hash table in which collisions are resolved by chaining, an unsuccessful search takes average-case time  $\Theta(1 + \alpha)$ , under the assumption of simple uniform hashing.

### Theorem 11.2

In a hash table in which collisions are resolved by chaining, a successful search takes average-case time  $\Theta(1 + \alpha)$  under the assumption of simple uniform hashing.

## Analysis of hashing: Constant time.

### Finally

These two theorems tell us that if  $n = O(m)$

$$\alpha = \frac{n}{m} = \frac{O(m)}{m} = O(1)$$

Or search time is constant.

## Analysis of hashing: Which hash function?

### Consider that:

Good hash functions should maintain the property of simple uniform hashing!

- The keys have the same probability  $1/m$  to be hashed to any bucket!!!
- A uniform hash function minimizes the likelihood of an overflow when keys are selected at random.

# Analysis of hashing: Which hash function?

## Consider that:

Good hash functions should maintain the property of simple uniform hashing!

- The keys have the same probability  $1/m$  to be hashed to any bucket!!!
- A uniform hash function minimizes the likelihood of an overflow when keys are selected at random.

## When:

What should we use?

- If we know how the keys are distributed uniformly at the following interval  $0 \leq k < 1$  then  $h(k) = \lfloor km \rfloor$ .

# Analysis of hashing: Which hash function?

## Consider that:

Good hash functions should maintain the property of simple uniform hashing!

# What if...

## Question:

What about something with keys in a normal distribution?

# Possible hash functions when the keys are natural numbers

## The division method

- $h(k) = k \bmod m.$

- Good choices for  $m$  are primes not too close to a power of 2.

# Possible hash functions when the keys are natural numbers

## The division method

- $h(k) = k \bmod m$ .
- Good choices for  $m$  are primes not too close to a power of 2.

## The multiplication method

- $h(k) = \lfloor m(kA \bmod 1) \rfloor$  with  $0 < A < 1$ .
- The value of  $m$  is not critical.
- Easy to implement in a computer.

When they are not, we need to interpreting the keys as natural numbers

### Keys interpreted as natural numbers

Given a string “pt”, we can say  $p = 112$  and  $t=116$  (ASCII numbers)

- ASCII has 128 possible symbols.
  - ▶ Then  $(128 \times 112) + 128^0 \times 116 = 14452$

Nevertheless

This is highly dependent on the origins of the keys!!!

When they are not, we need to interpreting the keys as natural numbers

## Hashing methods: The division method

### Hash function

$$h(k) = k \bmod m$$

# Hashing methods: The division method

## Hash function

$$h(k) = k \bmod m$$

## Problems with some selections

- $m = 2^p$ ,  $h(k)$  is only the  $p$  lowest-order bits.
- $m = 2^p - 1$ , when  $k$  is interpreted as a character string interpreted in radix  $2^p$ , permuting characters in  $k$  does not change the value.

# Hashing methods: The division method

## Hash function

$$h(k) = k \bmod m$$

## Problems with some selections

- $m = 2^p$ ,  $h(k)$  is only the  $p$  lowest-order bits.
- $m = 2^p - 1$ , when  $k$  is interpreted as a character string interpreted in radix  $2^p$ , permuting characters in  $k$  does not change the value.

## This better selection

- Prime numbers not too close to an exact power of two.
  - ▶ For example, given  $n = 2000$  elements.
    - ★ We can use  $m = 701$  because it is near to  $2000/3$  but not near a power of two.

# Hashing methods: The division method

## Hash function

$$h(k) = k \bmod m$$

## Problems with some selections

- $m = 2^p$ ,  $h(k)$  is only the  $p$  lowest-order bits.
- $m = 2^p - 1$ , when  $k$  is interpreted as a character string interpreted in radix  $2^p$ , permuting characters in  $k$  does not change the value.

## It is better to select

- Prime numbers not too close to an exact power of two.
  - For example, given  $n = 2000$  elements.
  - We can use  $m = 701$  because it is near to  $2000/3$  but not near a power of two.

## Hashing methods: The multiplication method

The multiplication method for creating hash functions has two steps

- 1 Multiply the key  $k$  by a constant  $A$  in the range  $0 < A < 1$  and extract the fractional part of  $kA$ .
- 2 Then, you multiply the value by  $m$  and take the floor,  
$$h(k) = \lfloor m(kA \bmod 1) \rfloor.$$

## Hashing methods: The multiplication method

The multiplication method for creating hash functions has two steps

- 1 Multiply the key  $k$  by a constant  $A$  in the range  $0 < A < 1$  and extract the fractional part of  $kA$ .
- 2 Then, you multiply the value by  $m$  and take the floor,  
$$h(k) = \lfloor m (kA \bmod 1) \rfloor.$$

The mod allows to extract the fractional part!!

$$kA \bmod 1 = kA - \lfloor kA \rfloor, 0 < A < 1.$$

## Hashing methods: The multiplication method

The multiplication method for creating hash functions has two steps

- 1 Multiply the key  $k$  by a constant  $A$  in the range  $0 < A < 1$  and extract the fractional part of  $kA$ .
- 2 Then, you multiply the value by  $m$  and take the floor,  
$$h(k) = \lfloor m (kA \bmod 1) \rfloor.$$

The mod allows to extract that fractional part!!!

$$kA \bmod 1 = kA - \lfloor kA \rfloor, 0 < A < 1.$$

$m$  is not critical, normally  $m = 2^p$ .

## Hashing methods: The multiplication method

The mod allows to extract that fractional part!!!

$$kA \bmod 1 = kA - \lfloor kA \rfloor, 0 < A < 1.$$

Advantages:

$m$  is not critical, normally  $m = 2^p$ .

# Implementing in a computer

## First

First, imagine that the word in a machine has  $w$  **bits size** and  $k$  fits on those bits.

## Second

Then, select an  $s$  in the range  $0 < s < 2^w$  and assume  $A = \frac{s}{2^w}$ .

## Third

Now, we multiply  $k$  by the number  $s = A2^w$ .

# Implementing in a computer

## First

First, imagine that the word in a machine has  $w$  **bits size** and  $k$  fits on those bits.

## Second

Then, select an  $s$  in the range  $0 < s < 2^w$  and assume  $A = \frac{s}{2^w}$ .

Now, we multiply  $k$  by the number  $s = A2^w$ .

However

## Sooner or Latter

We can pick up a hash function that does not give us the desired uniform randomized property

This

We are required to analyze the possible clustering of the data by the hash function

However

### Sooner or Latter

We can pick up a hash function that does not give us the desired uniform randomized property

### Thus

We are required to analyze the possible clustering of the data by the hash function

However

Unfortunately

Hash table do not give a way to measure clustering

Thus, table designers

They should provide some clustering estimation as part of the interface.

Thus

The clustering measure needs an estimate of the variance of the distribution of bucket sizes.

# Measuring Clustering through a metric $C$

## Definition

If bucket  $i$  contains  $n_i$  elements, then

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right] \quad (2)$$

# Measuring Clustering through a metric $C$

## Definition

If bucket  $i$  contains  $n_i$  elements, then

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right] \quad (2)$$

## Properties

- If  $C = 1$ , then you have uniform hashing.
- If  $C > 1$ , it means that the performance of the hash table is slowed down by clustering by approximately a factor of  $C$ .
- If  $C < 1$ , the spread of the elements is more even than uniform!!! Not going to happen!!!

# Measuring Clustering through a metric $C$

## Definition

If bucket  $i$  contains  $n_i$  elements, then

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right] \quad (2)$$

## Properties

- 1 If  $C = 1$ , then you have uniform hashing.
- 2 If  $C > 1$ , it means that the performance of the hash table is slowed down by clustering by approximately a factor of  $C$ .
- 3 If  $C < 1$ , the spread of the elements is more even than uniform!!! Not going to happen!!!

# Measuring Clustering through a metric $C$

# Thus

## First

If clustering is occurring, some buckets will have more elements than they should, and some will have fewer.

## Second

There will be a wider range of bucket sizes than one would expect from a random hash function.

# Thus

## First

If clustering is occurring, some buckets will have more elements than they should, and some will have fewer.

## Second

There will be a **wider range of bucket sizes** than one would expect from a random hash function.

## 5 Exercises

## Analysis of $C$

Consider the following random variable

Consider bucket  $i$  containing  $n_i$  elements, with  $X_{ij} = I\{\text{element } j \text{ lands in bucket } i\}$

Then, given

$$n_i = \sum_{j=1}^n X_{ij} \quad (3)$$

We have, given the uniform hash property that

$$E[X_{ij}] = \frac{1}{m}, \quad E[X_{ij}^2] = \frac{1}{m} \quad (4)$$

## Analysis of $C$

Consider the following random variable

Consider bucket  $i$  containing  $n_i$  elements, with  $X_{ij} = I\{\text{element } j \text{ lands in bucket } i\}$

Then, given

$$n_i = \sum_{j=1}^n X_{ij} \quad (3)$$

We have, given the uniform hash property that

$$E[X_{ij}] = \frac{1}{m}, \quad E[X_{ij}^2] = \frac{1}{m} \quad (4)$$

## Analysis of $C$

Consider the following random variable

Consider bucket  $i$  containing  $n_i$  elements, with  $X_{ij} = I\{\text{element } j \text{ lands in bucket } i\}$

Then, given

$$n_i = \sum_{j=1}^n X_{ij} \quad (3)$$

We have, given the uniform hash property that

$$E[X_{ij}] = \frac{1}{m}, \quad E[X_{ij}^2] = \frac{1}{m} \quad (4)$$

## We look at the Variance of $X_{ij}$

### We look at the dispersion of $X_{ij}$

$$\text{Var} [X_{ij}] = E [X_{ij}^2] - (E [X_{ij}])^2 = \frac{1}{m} - \frac{1}{m^2} \quad (5)$$

What about the expected number of elements at each bucket?

$$E [n_i] = E \left[ \sum_{j=1}^n X_{ij} \right] = \frac{n}{m} = \alpha \quad (6)$$

We look at the Variance of  $X_{ij}$

We look at the dispersion of  $X_{ij}$

$$\text{Var} [X_{ij}] = E [X_{ij}^2] - (E [X_{ij}])^2 = \frac{1}{m} - \frac{1}{m^2} \quad (5)$$

What about the expected number of elements at each bucket?

$$E [n_i] = E \left[ \sum_{j=1}^n X_{ij} \right] = \frac{n}{m} = \alpha \quad (6)$$

Then, we have given independence of  $\{X_{ij}\}$

Because independence of  $\{X_{ij}\}$ , the scattering of  $n_i$

$$\begin{aligned} \text{Var} [n_i] &= \text{Var} \left[ \sum_{j=1}^n X_{ij} \right] \\ &= \sum_{j=1}^n \text{Var} [X_{ij}] \\ &= n \text{Var} [X_{ij}] \end{aligned}$$

Then, we have given independence of  $\{X_{ij}\}$

Because independence of  $\{X_{ij}\}$ , the scattering of  $n_i$

$$\begin{aligned} \text{Var} [n_i] &= \text{Var} \left[ \sum_{j=1}^n X_{ij} \right] \\ &= \sum_{j=1}^n \text{Var} [X_{ij}] \\ &= n \text{Var} [X_{ij}] \end{aligned}$$

Then, we have given independence of  $\{X_{ij}\}$

Because independence of  $\{X_{ij}\}$ , the scattering of  $n_i$

$$\begin{aligned} \text{Var} [n_i] &= \text{Var} \left[ \sum_{j=1}^n X_{ij} \right] \\ &= \sum_{j=1}^n \text{Var} [X_{ij}] \\ &= n \text{Var} [X_{ij}] \end{aligned}$$

Then

What about the dispersion of possible number of elements at each bucket?

$$\text{Var} [n_i] = E [n_i^2] - (E [n_i])^2$$

But, we have that

Then

What about the dispersion of possible number of elements at each bucket?

$$\text{Var} [n_i] = E [n_i^2] - (E [n_i])^2$$

But, we have that

$$E [n_i^2] = E \left[ \sum_{j=1}^n X_{ij}^2 + \sum_{j=1}^n \sum_{k=1, k \neq j}^n X_{ij} X_{ik} \right] \quad (7)$$

Then

What about the dispersion of possible number of elements at each bucket?

$$\text{Var} [n_i] = E [n_i^2] - (E [n_i])^2$$

But, we have that

$$E [n_i^2] = E \left[ \sum_{j=1}^n X_{ij}^2 + \sum_{j=1}^n \sum_{k=1, k \neq j}^n X_{ij} X_{ik} \right] \quad (7)$$

Or

$$E [n_i^2] = \frac{n}{m} + \sum_{j=1}^n \sum_{k=1, k \neq j}^n \frac{1}{m^2} \quad (8)$$

Thus

We re-express the range on term of expected values of  $n_i$

$$E \left[ n_i^2 \right] = \frac{n}{m} + \frac{n(n-1)}{m^2} \quad (9)$$

Then

Thus

We re-express the range on term of expected values of  $n_i$

$$E [n_i^2] = \frac{n}{m} + \frac{n(n-1)}{m^2} \quad (9)$$

Then

$$\begin{aligned} \text{Var} (n_i) &= E [n_i^2] - E [n_i]^2 = \frac{n}{m} + \frac{n(n-1)}{m^2} - \frac{n^2}{m^2} \\ &= \frac{n}{m} - \frac{n}{m^2} \\ &= \alpha - \frac{\alpha}{m} \end{aligned}$$

Thus

We re-express the range on term of expected values of  $n_i$

$$E [n_i^2] = \frac{n}{m} + \frac{n(n-1)}{m^2} \quad (9)$$

Then

$$\begin{aligned} \text{Var} (n_i) &= E [n_i^2] - E [n_i]^2 = \frac{n}{m} + \frac{n(n-1)}{m^2} - \frac{n^2}{m^2} \\ &= \frac{n}{m} - \frac{n}{m^2} \end{aligned}$$

Thus

We re-express the range on term of expected values of  $n_i$

$$E [n_i^2] = \frac{n}{m} + \frac{n(n-1)}{m^2} \quad (9)$$

Then

$$\begin{aligned} \text{Var} (n_i) &= E [n_i^2] - E [n_i]^2 = \frac{n}{m} + \frac{n(n-1)}{m^2} - \frac{n^2}{m^2} \\ &= \frac{n}{m} - \frac{n}{m^2} \\ &= \alpha - \frac{\alpha}{m} \end{aligned}$$

Then, we have that

Now we build an estimator of the mean of  $n_i^2$  which is part of

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right]$$

$$\frac{1}{n} \sum_{i=1}^m n_i^2 \quad (10)$$

Thus, we ask what is the expected value of the mean of the variances

Then, we have that

Now we build an estimator of the mean of  $n_i^2$  which is part of

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right]$$

$$\frac{1}{n} \sum_{i=1}^m n_i^2 \quad (10)$$

Thus, we ask what is the expected value of the mean of the variances

$$\begin{aligned} E \left[ \frac{1}{n} \sum_{i=1}^m n_i^2 \right] &= \frac{1}{n} \sum_{i=1}^m E \left[ n_i^2 \right] \\ &= \frac{m}{n} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= \frac{1}{\alpha} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= 1 - \frac{1}{m} + \alpha \end{aligned}$$

Then, we have that

Now we build an estimator of the mean of  $n_i^2$  which is part of

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right]$$

$$\frac{1}{n} \sum_{i=1}^m n_i^2 \quad (10)$$

Thus, we ask what is the expected value of the mean of the variances

$$\begin{aligned} E \left[ \frac{1}{n} \sum_{i=1}^m n_i^2 \right] &= \frac{1}{n} \sum_{i=1}^m E \left[ n_i^2 \right] \\ &= \frac{m}{n} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= \frac{1}{\alpha} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= 1 - \frac{1}{m} + \alpha \end{aligned}$$

Then, we have that

Now we build an estimator of the mean of  $n_i^2$  which is part of

$$C = \frac{m}{n-1} \left[ \frac{\sum_{i=1}^m n_i^2}{n} - 1 \right]$$

$$\frac{1}{n} \sum_{i=1}^m n_i^2 \quad (10)$$

Thus, we ask what is the expected value of the mean of the variances

$$\begin{aligned} E \left[ \frac{1}{n} \sum_{i=1}^m n_i^2 \right] &= \frac{1}{n} \sum_{i=1}^m E \left[ n_i^2 \right] \\ &= \frac{m}{n} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= \frac{1}{\alpha} \left[ \alpha \left( 1 - \frac{1}{m} \right) + \alpha^2 \right] \\ &= 1 - \frac{1}{m} + \alpha \end{aligned}$$

Finally, we analyze the Expected Value of  $C$  under uniform hashing

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ 1 - \frac{1}{m} + \alpha - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{n}{m} - \frac{1}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{n-1}{m} \right] \\ &= 1 \end{aligned}$$

Finally, we analyze the Expected Value of  $C$  under uniform hashing

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ 1 - \frac{1}{m} + \alpha - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{n}{m} - \frac{1}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{n-1}{m} \right] \\ &= 1 \end{aligned}$$

Finally, we analyze the Expected Value of  $C$  under uniform hashing

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ 1 - \frac{1}{m} + \alpha - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{n}{m} - \frac{1}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{n-1}{m} \right] \\ &= 1 \end{aligned}$$

Finally, we analyze the Expected Value of  $C$  under uniform hashing

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ 1 - \frac{1}{m} + \alpha - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{n}{m} - \frac{1}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{n-1}{m} \right] \\ &= 1 \end{aligned}$$

Finally, we analyze the Expected Value of  $C$  under uniform hashing

## 5 Exercises

Now, we have a really horrible hash function  $\equiv$  It hits only one of every  $b$  buckets

Thus

$$E[X_{ij}] = E[X_{ij}^2] = \frac{b}{m} \quad (11)$$

Thus, we have

$$E[n_i] = \alpha b \quad (12)$$

Then, we have

$$\begin{aligned} E\left[\frac{1}{n} \sum_{i=1}^m n_i^2\right] &= \frac{1}{n} \sum_{i=1}^m E[n_i^2] \\ &= \alpha b - \frac{b}{m} + 1 \end{aligned}$$

Now, we have a really horrible hash function  $\equiv$  It hits only one of every  $b$  buckets

Thus

$$E[X_{ij}] = E[X_{ij}^2] = \frac{b}{m} \quad (11)$$

Thus, we have

$$E[n_i] = \alpha b \quad (12)$$

Then, we have

$$\begin{aligned} E\left[\frac{1}{n} \sum_{i=1}^m n_i^2\right] &= \frac{1}{n} \sum_{i=1}^m E[n_i^2] \\ &= \alpha b - \frac{b}{m} + 1 \end{aligned}$$

Now, we have a really horrible hash function  $\equiv$  It hits only one of every  $b$  buckets

Thus

$$E[X_{ij}] = E[X_{ij}^2] = \frac{b}{m} \quad (11)$$

Thus, we have

$$E[n_i] = \alpha b \quad (12)$$

Then, we have

$$\begin{aligned} E\left[\frac{1}{n} \sum_{i=1}^m n_i^2\right] &= \frac{1}{n} \sum_{i=1}^m E[n_i^2] \\ &= \alpha b - \frac{b}{m} + 1 \end{aligned}$$

## Finally

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ \alpha b - \frac{b}{m} + 1 - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{nb}{m} - \frac{b}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{b(n-1)}{m} \right] \\ &= b \end{aligned}$$

## Finally

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ \alpha b - \frac{b}{m} + 1 - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{nb}{m} - \frac{b}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{b(n-1)}{m} \right] \\ &= b \end{aligned}$$

## Finally

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ \alpha b - \frac{b}{m} + 1 - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{nb}{m} - \frac{b}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{b(n-1)}{m} \right] \\ &= b \end{aligned}$$

## Finally

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ \alpha b - \frac{b}{m} + 1 - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{nb}{m} - \frac{b}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{b(n-1)}{m} \right] \\ &= b \end{aligned}$$

## Finally

We can plug back on  $C$  using the expected value

$$\begin{aligned} E[C] &= \frac{m}{n-1} \left[ E \left[ \frac{\sum_{i=1}^m n_i^2}{n} \right] - 1 \right] \\ &= \frac{m}{n-1} \left[ \alpha b - \frac{b}{m} + 1 - 1 \right] \\ &= \frac{m}{n-1} \left[ \frac{nb}{m} - \frac{b}{m} \right] \\ &= \frac{m}{n-1} \left[ \frac{b(n-1)}{m} \right] \\ &= b \end{aligned}$$

# Explanation

Using a hash table that enforce a uniform distribution in the buckets

- We get that  $C = b > 1$  or a really bad distribution of the keys!!!

Thus, you only need the following to evaluate a hash function

$$\frac{1}{n} \sum_{i=1}^m n_i^2 \quad (13)$$

# Explanation

# Definition of Universal Hash Functions

## Definition

Let  $H = \{h : U \rightarrow \{0, 1, \dots, m - 1\}\}$  be a family of hash functions.  $H$  is called a universal family if

$$\forall x, y \in U, x \neq y : \Pr_{h \in H}(h(x) = h(y)) \leq \frac{1}{m} \quad (14)$$

## Main result

With universal hashing the chance of collision between distinct keys  $k$  and  $l$  is no more than the  $\frac{1}{m}$  chance of collision if locations  $h(k)$  and  $h(l)$  were randomly and independently chosen from the set  $\{0, 1, \dots, m - 1\}$ .

# Definition of Universal Hash Functions

## Definition

Let  $H = \{h : U \rightarrow \{0, 1, \dots, m - 1\}\}$  be a family of hash functions.  $H$  is called a universal family if

$$\forall x, y \in U, x \neq y : \Pr_{h \in H}(h(x) = h(y)) \leq \frac{1}{m} \quad (14)$$

## Main result

With universal hashing the chance of collision between distinct keys  $k$  and  $l$  is no more than the  $\frac{1}{m}$  chance of collision if locations  $h(k)$  and  $h(l)$  were randomly and independently chosen from the set  $\{0, 1, \dots, m - 1\}$ .

# Universal Hashing

## Theorem 11.3

- Suppose that a hash function  $h$  is chosen randomly from a universal collection of hash functions and has been used to hash  $n$  keys into a table  $T$  of size  $m$ , using chaining to resolve collisions.
- If key  $k$  is not in the table, then the expected length  $E[n_{h(k)}]$  of the list that key  $k$  hashes to is at most the load factor  $\alpha = \frac{n}{m}$ . If key  $k$  is in the table, then the expected length  $E[n_{h(k)}]$  of the list containing key  $k$  is at most  $1 + \alpha$ .

# Universal Hashing

## Theorem 11.3

- Suppose that a hash function  $h$  is chosen randomly from a universal collection of hash functions and has been used to hash  $n$  keys into a table  $T$  of size  $m$ , using chaining to resolve collisions.
- If key  $k$  is not in the table, then the expected length  $E[n_{h(k)}]$  of the list that key  $k$  hashes to is at most the load factor  $\alpha = \frac{n}{m}$ . If key  $k$  is in the table, then the expected length  $E[n_{h(k)}]$  of the list containing key  $k$  is at most  $1 + \alpha$ .

Using universal hashing and collision resolution by chaining in an initially empty table with  $m$  slots, it takes expected time  $\Theta(n)$  to handle any sequence of  $n$  INSERT, SEARCH, and DELETE operations  $O(m)$  INSERT operations.

# Universal Hashing

## Theorem 11.3

- Suppose that a hash function  $h$  is chosen randomly from a universal collection of hash functions and has been used to hash  $n$  keys into a table  $T$  of size  $m$ , using chaining to resolve collisions.
- If key  $k$  is not in the table, then the expected length  $E[n_{h(k)}]$  of the list that key  $k$  hashes to is at most the load factor  $\alpha = \frac{n}{m}$ . If key  $k$  is in the table, then the expected length  $E[n_{h(k)}]$  of the list containing key  $k$  is at most  $1 + \alpha$ .

## Corollary 11.4

Using universal hashing and collision resolution by chaining in an initially empty table with  $m$  slots, it takes expected time  $\Theta(n)$  to handle any sequence of  $n$  INSERT, SEARCH, and DELETE operations  $O(m)$  INSERT operations.

# Example of Universal Hash

## Proceed as follows:

- Choose a primer number  $p$  large enough so that every possible key  $k$  is in the range  $[0, \dots, p - 1]$

$$Z_p = \{0, 1, \dots, p - 1\} \text{ and } Z_p^* = \{1, \dots, p - 1\}$$

- Define the following hash function:

$$h_{a,b}(k) = ((ak + b) \bmod p) \bmod m, \forall a \in Z_p^* \text{ and } b \in Z_p$$

- The family of all such hash functions is:

$$H_{p,m} = \{h_{a,b} : a \in Z_p^* \text{ and } b \in Z_p\}$$

# Example of Universal Hash

## Proceed as follows:

- Choose a primer number  $p$  large enough so that every possible key  $k$  is in the range  $[0, \dots, p - 1]$

$$\mathbb{Z}_p = \{0, 1, \dots, p - 1\} \text{ and } \mathbb{Z}_p^* = \{1, \dots, p - 1\}$$

- Define the following hash function:

$$h_{a,b}(k) = ((ak + b) \bmod p) \bmod m, \forall a \in \mathbb{Z}_p^* \text{ and } b \in \mathbb{Z}_p$$

- The family of all such hash functions is:

$$H_{p,m} = \{h_{a,b} : a \in \mathbb{Z}_p^* \text{ and } b \in \mathbb{Z}_p\}$$

## Implementation

- $a$  and  $b$  are chosen randomly at the beginning of execution.
- The class  $H_{p,m}$  of hash functions is universal.

# Example of Universal Hash

An example of  $P(\Theta|X) = P(X|\Theta)P(\Theta)$

## Another Example: Matrix Method

### Then

- Let us say keys are  $u$ -bits long.
- Say the table size  $M$  is power of 2.
- an index is  $b$ -bits long with  $M = 2^b$ .

## Another Example: Matrix Method

### Then

- Let us say keys are  $u$ -bits long.
- Say the table size  $M$  is power of 2.
- an index is  $b$ -bits long with  $M = 2^b$ .

### The Hash Function

- Pick  $h$  to be a random  $b$ -by- $u$  0/1 matrix, and define  $h(x) = hx$  where after the inner product we apply mod 2

## Another Example: Matrix Method

### Then

- Let us say keys are  $u$ -bits long.
- Say the table size  $M$  is power of 2.
- an index is  $b$ -bits long with  $M = 2^b$ .

### This is implemented

- Pick  $h$  to be a random  $b$ -by- $u$  0/1 matrix, and define  $h(x) = hx$  where after the inner product we apply mod 2

### Example

$$b \begin{matrix} & h & & \\ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix} & \begin{matrix} x \\ \begin{bmatrix} 1 \\ 0 \\ 1 \\ 0 \end{bmatrix} \end{matrix} & = & \begin{matrix} h(x) \\ \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} \end{matrix} \\ & u & & \end{matrix}$$

## Another Example: Matrix Method

### Then

- Let us say keys are  $u$ -bits long.
- Say the table size  $M$  is power of 2.
- an index is  $b$ -bits long with  $M = 2^b$ .

### The $h$ function

- Pick  $h$  to be a random  $b$ -by- $u$  0/1 matrix, and define  $h(x) = hx$  where after the inner product we apply mod 2

$$b \begin{matrix} & h & & \\ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix} & \begin{matrix} \\ x \\ \\ \end{matrix} & = & \begin{matrix} h(x) \\ \\ \\ \end{matrix} \\ & u & & \end{matrix}$$

## Another Example: Matrix Method

### Then

- Let us say keys are  $u$ -bits long.
- Say the table size  $M$  is power of 2.
- an index is  $b$ -bits long with  $M = 2^b$ .

### The $h$ function

- Pick  $h$  to be a random  $b$ -by- $u$  0/1 matrix, and define  $h(x) = hx$  where after the inner product we apply mod 2

### Example

$$b \begin{matrix} & h & & \\ \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix} & & \begin{matrix} x \\ \begin{bmatrix} 1 \\ 0 \\ 1 \\ 0 \end{bmatrix} \end{matrix} & = & \begin{matrix} h(x) \\ \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} \end{matrix} \\ & u & & \end{matrix}$$

# First than anything

## What is the meaning of multiply $h$ by $x$

- We can think of it as adding some of the columns of  $h$  where the 1 bits in indicate which to add
- Without losing generality assume the following

# First than anything

## What is the meaning of multiply $h$ by $x$

- We can think of it as adding some of the columns of  $h$  where the 1 bits in indicate which to add
- Without losing generality assume the following
  - 1  $l_i \neq m_i \Rightarrow$  for example  $l_i = 0$  and  $m_i = 1$

$l_j = m_j \forall j \neq i$

# First than anything

## What is the meaning of multiply $h$ by $x$

- We can think of it as adding some of the columns of  $h$  where the 1 bits in indicate which to add
- Without losing generality assume the following
  - 1  $l_i \neq m_i \Rightarrow$  for example  $l_i = 0$  and  $m_i = 1$
  - 2  $l_j = m_j \forall j \neq i$

## Now Proof of being a Universal Family

### Thus

- The column  $i$  does not contribute to the final answer of  $h(l)$  because of the zero!!!

$$b \begin{matrix} & h & & & \\ \begin{bmatrix} 1 & \mathbf{0} & 0 & 0 \\ 0 & \mathbf{1} & 1 & 1 \\ 1 & \mathbf{1} & 1 & 0 \end{bmatrix} & & & & \\ & u & & & \end{matrix} \begin{matrix} x \\ \begin{bmatrix} 1 \\ \mathbf{0} \\ 1 \\ 0 \end{bmatrix} \end{matrix} = \begin{matrix} h(x) \\ \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} \end{matrix}$$

### Now

- Imagine that we fix all the other columns in  $h$ , and we allow the  $i$ th column you have free choices

## Now Proof of being a Universal Family

### Thus

- The column  $i$  does not contribute to the final answer of  $h(l)$  because of the zero!!!

$$b \begin{matrix} & h & & & \\ \begin{bmatrix} 1 & \mathbf{0} & 0 & 0 \\ 0 & \mathbf{1} & 1 & 1 \\ 1 & \mathbf{1} & 1 & 0 \end{bmatrix} & & & & \\ & u & & & \end{matrix} \begin{matrix} x \\ \begin{bmatrix} 1 \\ \mathbf{0} \\ 1 \\ 0 \end{bmatrix} \end{matrix} = \begin{matrix} h(x) \\ \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} \end{matrix}$$

### Now

- Imagine that we fix all the other columns in  $h$ , and we allow the  $i^{th}$  column you have free choices

## Now, we do something strange

But having  $x_i = 0$  make  $h(x)$  to have a fix value, for example

$$\begin{bmatrix} 1 & 0 & \mathbf{0} & 0 \\ 0 & 1 & \mathbf{1} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{0} \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

In the contrary we have  $y_i$  and with respect to a specific flipping column of  $h$

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

Now, we do something strange

But having  $x_i = 0$  make  $h(x)$  to have a fix value, for example

$$\begin{bmatrix} 1 & 0 & \mathbf{0} & 0 \\ 0 & 1 & \mathbf{1} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{0} \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$$

In the contrary, we have  $y$  and with respect to a specific flipping column of  $h$

$$\begin{bmatrix} 1 & 0 & \mathbf{0} & 0 \\ 0 & 1 & \mathbf{1} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{1} \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$$

## We have others

For example

$$\begin{bmatrix} 1 & 0 & \mathbf{1} & 0 \\ 0 & 1 & \mathbf{0} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{1} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

How many of them, when flipping on the  $i^{\text{th}}$  column.

$$2^b$$

## We have others

For example

$$\begin{bmatrix} 1 & 0 & \mathbf{1} & 0 \\ 0 & 1 & \mathbf{0} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{1} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

How many of them, when flipping on the  $i^{\text{th}}$  column

$$2^b$$

Even the one that looks like

We have

$$\begin{bmatrix} 1 & 0 & \mathbf{0} & 0 \\ 0 & 1 & \mathbf{0} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{1} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

What is the probability of getting the same values i.e.

$$h(l) = h(m)$$

Even the one that looks like

We have

$$\begin{bmatrix} 1 & 0 & \mathbf{0} & 0 \\ 0 & 1 & \mathbf{0} & 1 \\ 1 & 1 & \mathbf{1} & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \\ \mathbf{1} \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

What is the probability of getting the same values i.e.

$$h(l) = h(m)$$

## Quite easy

Thus, given the randomness of the zeros and ones

- The probability that we get equality is

$$P(h(l) = h(m)) = \frac{1}{2^b}$$

Or more formally

$$P(h(l) = h(m)) \leq \frac{1}{2^b}$$

## Quite easy

Thus, given the randomness of the zeros and ones

- The probability that we get equality is

$$P(h(l) = h(m)) = \frac{1}{2^b}$$

Or more formally

$$P(h(l) = h(m)) \leq \frac{1}{2^b}$$

## Implementation of the column\*vector mod 2

### Code

```
int product(int row, int vector){  
  
    int i = row & vector;  
  
    i = i - ((i >> 1) & 0x55555555);  
    i = (i & 0x33333333) + ((i >> 2) & 0x33333333);  
    i = (((i + (i >> 4)) & 0x0F0F0F0F) * 0x01010101) >> 24;  
  
    return i & i & 0x00000001;  
  
}
```

# Advantages of universal hashing

## Advantages

- Universal hashing provides good results on average, independently of the keys to be stored.
- Guarantees that no input will always elicit the worst-case behavior.
- Poor performance occurs only when the random choice returns an inefficient hash function; this has a small probability.

# Advantages of universal hashing

# Open addressing

## Definition

All the elements occupy the hash table itself.

## What is it?

We systematically examine table slots until either we find the desired element or we have ascertained that the element is not in the table.

## Advantages

The advantage of open addressing is that it avoids pointers altogether.

# Insert in Open addressing

## Extended hash function to **probe**

- Instead of being fixed in the order  $0, 1, 2, \dots, m - 1$  with  $\Theta(n)$  search time.
- Extend the hash function to  
$$h : U \times \{0, 1, \dots, m - 1\} \rightarrow \{0, 1, \dots, m - 1\}.$$
- This gives the probe sequence  $\langle h(k, 0), h(k, 1), \dots, h(k, m - 1) \rangle$ .
  - ▶ A permutation of  $\{0, 1, 2, \dots, m - 1\}$

# Linear probing: Definition and properties

## Hash function

- Given an ordinary hash function  $h' : U \rightarrow \{0, 1, \dots, m - 1\}$  for  $i = 0, 1, \dots, m - 1$ , we get the extended hash function

$$h(k, i) = (h'(k) + i) \pmod{m}, \quad (15)$$

## Sequence of probes

Given key  $k$ , we first probe  $T[h'(k)]$ , then  $T[h'(k) + 1]$  and so on until  $T[m - 1]$ . Then, we wrap around  $T[0]$  to  $T[h'(k) - 1]$ .

## Distinct probes

Because the initial probe determines the entire probe sequence, there are  $m$  distinct probe sequences.

# Linear probing: Definition and properties

## Hash function

## Distinct probes

Because the initial probe determines the entire probe sequence, there are  $m$  distinct probe sequences.

# Linear probing: Definition and properties

## Disadvantages

- Linear probing suffers of primary clustering.
- Long runs of occupied slots build up increasing the average search time.
- Long runs of occupied slots tend to get longer, and the average search time increases.

# Linear probing: Definition and properties

## Disadvantages

- Linear probing suffers of primary clustering.
- Long runs of occupied slots build up increasing the average search time.

- Long runs of occupied slots build up increasing the average search time.
- Long runs of occupied slots tend to get longer, and the average search time increases.

# Why?

Clusters arise because an empty slot preceded by  $i$  full slots gets filled next with probability  $\frac{i+1}{m}$ .

Thus

The probability of getting a collision increases dramatically after each insertion.

## Why?

Clusters arise because an empty slot preceded by  $i$  full slots gets filled next with probability  $\frac{i+1}{m}$ .

## Thus

The probability of getting a collision increases dramatically after each insertion.

# Linear Probing – Remove

## Example

0		4			8			12			16				
34	0	45			6	23	7			28	12	29	11	30	33

remove(0)

Compact Cluster

Search cluster for pair (if any) to fill vacated bucket.

# Linear Probing – Remove

## Example

0		4		8		12		16							
34	0	45			6	23	7			28	12	29	11	30	33

## remove(0)

0		4		8		12		16							
34		45			6	23	7			28	12	29	11	30	33

Computer Cluster

Search cluster for pair (if any) to fill vacated bucket.

# Linear Probing – Remove

## Example

0	4	8	12	16											
34	0	45			6	23	7			28	12	29	11	30	33

## remove(0)

0	4	8	12	16											
34		45			6	23	7			28	12	29	11	30	33

## Compact Cluster

Search cluster for pair (if any) to fill vacated bucket.

0	4	8	12	16

## Example

0	4	8	12	16											
34	0	45			6	23	7			28	12	29	11	30	33

0	4	8	12	16											
34	0	45			6	23	7			28	12		11	30	33

Comparator Cluster

Search cluster for pair (if any) to fill vacated bucket.

## Linear Probing – remove(29)

### Example

0	4	8	12	16											
34	0	45			6	23	7			28	12	29	11	30	33

0	4	8	12	16											
34	0	45			6	23	7			28	12		11	30	33

### Compact Cluster

Search cluster for pair (if any) to fill vacated bucket.

0	4	8	12	16											
34	0	45			6	23	7			28	12	11		30	33

0	4	8	12	16											
34	0	45			6	23	7			28	12	11	30		33

0	4	8	12	16											
34	0				6	23	7			28	12	11	30	45	33

## Code for Removing

We have the following

```
public void remove(key){
    int positionsChecked = 1;
    int i = FindSlot(Key);
    if (Table[i] == null)
        return;    // key is not in the table
    j = i;
    while(positionsChecked <= Table.length){
        j = (j+1) % Table.length;
        if (Table[j] == null) break;
        k = Hashing(Table[j].key);
        if (i < j && (k <= i || k > j)) ||
            (j < i && (k <= i && k > j)) {
            Table[i] = Table[j];
            i = j;
        }
        positionChecked++;
    }
    Table[i] = null;
}
```

# Explanation

## First

For all records in a cluster, there must be no vacant slots between their natural hash position and their current position (else lookups will terminate before finding the record).

## Second

- $k$  is the raw hash where the record at  $j$  would naturally land in the hash table if there were no collisions.

## Third

This test is asking if the record at  $j$  is invalidly positioned with respect to the required properties of a cluster now that  $i$  is vacant.

# Explanation

## First

For all records in a cluster, there must be no vacant slots between their natural hash position and their current position (else lookups will terminate before finding the record).

## Second

- $k$  is the raw hash where the record at  $j$  would naturally land in the hash table if there were no collisions.

This test is asking if the record at  $j$  is invalidly positioned with respect to the required properties of a cluster now that  $i$  is vacant.

# Explanation

## First

For all records in a cluster, there must be no vacant slots between their natural hash position and their current position (else lookups will terminate before finding the record).

## Second

- $k$  is the raw hash where the record at  $j$  would naturally land in the hash table if there were no collisions.

## Thus

This test is asking if the record at  $j$  is invalidly positioned with respect to the required properties of a cluster now that  $i$  is vacant.

# Case 1

We have the following

Case 1

we have  $i < j$

- If  $i < k \leq j$  then moving  $j$  to the  $i$  position will be incorrect... Why?

## Case 2

We have the following

Case 2

We have  $j < i$

- If  $k \leq j <$  or  $i < k$  then moving  $j$  to the  $i$  position will be incorrect... Why?

## Quadratic probing: Definition and properties

### Hash function

- Given an auxiliary hash function  $h' : U \rightarrow \{0, 1, \dots, m - 1\}$  for  $i = 0, 1, \dots, m - 1$ , we get the extended hash function

$$h(k, i) = (h'(k) + c_1i + c_2i^2) \bmod m, \quad (16)$$

where  $c_1, c_2$  are auxiliary constants

# Quadratic probing: Definition and properties

## Hash function

- Given an auxiliary hash function  $h' : U \rightarrow \{0, 1, \dots, m - 1\}$  for  $i = 0, 1, \dots, m - 1$ , we get the extended hash function

$$h(k, i) = (h'(k) + c_1i + c_2i^2) \pmod{m}, \quad (16)$$

where  $c_1, c_2$  are auxiliary constants

## Sequences of probes

- Given key  $k$ , we first probe  $T[h'(k)]$ , later positions probed are offset by amounts that depend in a quadratic manner on the probe number  $i$ .
- The initial probe determines the entire sequence, and so only  $m$  distinct probe sequences are used.

# Quadratic probing: Definition and properties

- The initial probe determines the entire sequence, and so only  $m$  distinct probe sequences are used.

# Quadratic probing: Definition and properties

## Advantages

This method works much better than linear probing, but to make full use of the hash table, the values of  $c_1, c_2$ , and  $m$  are constrained.

## Disadvantages

If two keys have the same initial probe position, then their probe sequences are the same, since  $h(k_1, 0) = h(k_2, 0)$  implies  $h(k_1, i) = h(k_2, i)$ . This property leads to a milder form of clustering, called secondary clustering.

# Quadratic probing: Definition and properties

## 5 Exercises

## Definition and properties

### Hash function

Double hashing uses a hash function of the form

$$h(k, i) = (h_1(k) + ih_2(k)) \bmod m, \quad (17)$$

where  $i = 0, 1, \dots, m - 1$  and  $h_1, h_2$  are auxiliary hash functions (Normally for a Universal family)

# Definition and properties

## Hash function

Double hashing uses a hash function of the form

$$h(k, i) = (h_1(k) + ih_2(k)) \bmod m, \quad (17)$$

where  $i = 0, 1, \dots, m - 1$  and  $h_1, h_2$  are auxiliary hash functions (Normally for a Universal family)

## Sequences of probes

- Given key  $k$ , we first probe  $T[h_1(k)]$ , successive probe positions are offset from previous positions by the amount  $h_2(k) \bmod m$ .
- Thus, unlike the case of linear or quadratic probing, the probe sequence here depends in two ways upon the key  $k$ , since the initial probe position, the offset, or both, may vary.

# Definition and properties

## Hash function

- Thus, unlike the case of linear or quadratic probing, the probe sequence here depends in two ways upon the key  $k$ , since the initial probe position, the offset, or both, may vary.

# Definition and properties

## Advantages

- When  $m$  is prime or a power of 2, double hashing improves over linear or quadratic probing in that  $\Theta(m^2)$  probe sequences are used, rather than  $\Theta(m)$  since each possible  $(h_1(k), h_2(k))$  pair yields a distinct probe sequence.
- The performance of double hashing appears to be very close to the performance of the "ideal" scheme of uniform hashing.

# Definition and properties

# Analysis of Open Addressing

## Theorem 11.6

Given an open-address hash table with load factor  $\alpha = \frac{n}{m} < 1$ , the expected number of probes in an unsuccessful search is at most  $\frac{1}{1-\alpha}$  assuming uniform hashing.

## Corollary

Inserting an element into an open-address hash table with load factor  $\alpha$  requires at most  $\frac{1}{1-\alpha}$  probes on average, assuming uniform hashing.

## Theorem 11.8

Given an open-address hash table with load factor  $\alpha < 1$ , the expected number of probes in a successful search is at most  $\frac{1}{\alpha} \ln \frac{1}{1-\alpha}$  assuming uniform hashing and assuming that each key in the table is equally likely to be searched for.
