## 5 Exercises

- Some Exercises that you can try

# Disk-based Environments

## Something Notable

We have the following hierarchy of data access speed

- 1 CPU
- 2 Cache
- 3 Main Memory
- 4 Secondary Storage: Magnetic Disks and SSD
- 5 Tertiary Storage: Tapes

# Disk-based Environments

## Something Notable

We have the following hierarchy of data access speed

- 1 CPU
- 2 Cache
- 3 Main Memory
- 4 Secondary Storage: Magnetic Disks and SSD
- 5 Tertiary Storage: Tapes

## We know the following

- Data is stored on disk in units called blocks or pages.
- Every disk access has to read/write one or multiple blocks.
- Even if we need to access a single integer stored in a disk block which contains thousands of integers, we need to read the whole block in.

# Disk-based Environments

- 5 Tertiary Storage: Tapes

## We know the following

- Data is stored on disk in units called blocks or pages.
- Every disk access has to read/write one or multiple blocks.
- Even if we need to access a single integer stored in a disk block which contains thousands of integers, **we need to read the whole block in.**

## Now, What if you use a binary tree

In this structure the nodes are disk blocks

Still, We have the following problem

- If a disk block is 8K (8192 bytes)

## Now, What if you use a binary tree

In this structure the nodes are disk blocks

Still, We have the following problem

- If a disk block is 8K (8192 bytes)
- Problem the necessary information for a node is
  - ▶ A key = 4 bytes
  - ▶ A value = 4 bytes
  - ▶ Two Children = 8 bytes

## Now, What if you use a binary tree

In this structure the nodes are disk blocks

Still, We have the following problem

- If a disk block is 8K (8192 bytes)
- Problem the necessary information for a node is
  - ▶ A key = 4 bytes
  - ▶ A value = 4 bytes
  - ▶ Two Children = 8 bytes

# Problem!!!

Then

We use only 0.2% of the block is full

Even

If we store multiple tree nodes in a disk!!!

# Problem!!!

Then

We use only 0.2% of the block is full

Even

If we store multiple tree nodes in a disk!!!

However

The query and update need to access  $O(\log_2 n)$  nodes

**Worst Case  $O(\log_2 n)$  accesses to disk!!!**

# Increase the branching

With a large  $B$

$$\log_B n \ll \log_2 n \quad (1)$$

Ok

- We can minimize the number of disk access by increasing the branching!!!

# Increase the branching

With a large  $B$

$$\log_B n \ll \log_2 n \quad (1)$$

Ok

- We can minimize the number of disk access by increasing the branching!!!
- We need a way to access elements in the new branching.

# Motivation for B-Trees

## Some facts!

- Index structures for large datasets cannot be stored in main memory (Actually, not anymore the case!!!).
- Storing it on disk requires different approach to efficiency.
- Assuming that a disk spins at 3600 RPM, one revolution occurs in  $1/60$  of a second, or 16.7 ms.
- Crudely speaking, one disk access takes about the same time as 200,000 instructions!

# Motivation for B-Trees

# Motivation for B-Trees

## Now

- Assume that we use a binary tree to store about 20 million records.
  - We end up with a very deep binary tree with lots of different disk accesses;  $\log_2 20 \times 10^6$  is about 24, so this takes about 0.2 seconds.
  - We know we can't improve on the  $\log_2 n$  lower bound on search for a binary tree.
  - However, the solution is to use more branches and thus reduce the height of the tree! As branching increases, depth decreases.

# Motivation for B-Trees

# B-Trees definition

## Example

## Definitions

- Every node  $x$  has the following attributes:

# B-Trees definition

## Example

## Definitions

- Every node  $x$  has the following attributes:
  - ▶  $x.n$  number of keys stored at node  $x$ .
    - ★ Each key has an associated payload (Pointer, values, etc).
  - ▶ The keys are sorted  $key_1 \leq key_2 \leq \dots \leq key_{x.n}$ .
  - ▶  $x.leaf$  is a boolean value and denotes a leaf when is set to TRUE.

# B-Trees definition

## Example

## Definitions

- Every node  $x$  has the following attributes:
  - ▶  $x.n$  number of keys stored at node  $x$ .
    - ★ Each key has an associated payload (Pointer, values, etc).
  - ▶ The keys are sorted  $key_1 \leq key_2 \leq \dots \leq key_{x.n}$ .
  - ▶  $x.leaf$  is a boolean value and denotes a leaf when is set to TRUE.

# B-Trees definition

## Example

## Definitions

- Every node  $x$  has the following attributes:

    - ★ Each key has an associated payload (Pointer, values, etc).
  - ▶ The keys are sorted  $key_1 \leq key_2 \leq \dots \leq key_{x.n}$ .
  - ▶  $x.leaf$  is a boolean value and denotes a leaf when is set to TRUE.

# B-Trees definition

## Example

# B-Trees definition

## In addition

- Every node  $x$  has the following attributes:

- ▶ It contains  $x.n + 1$  pointers to its children:

$$x.c_1, x.c_2, \dots, x.c_{n+1}$$

- ★ Leaf nodes do not have children then they leave this field undefined.
- ★ The keys are used to separate the keys stored at the B-Tree. For example, if  $k_i$  is any key stored in the subtree stored at tree with root  $x.c_i$ , then

$$k_1 \leq x.key_1 \leq k_2 \leq x.key_2 \leq \dots \leq x.key_n \leq k_{n+1}$$

# B-Trees definition

## In addition

- Every node  $x$  has the following attributes:
  - ▶ It contains  $x.n + 1$  pointers to its children:

$$x.c_1, x.c_2, \dots, x.c_{n+1}$$

- ★ Leaf nodes do not have children then they leave this field undefined.

# We want to store large sets of indexes

## First

We assume that the set is so voluminous that only a small part can be kept in main memory!!!

## Hints

We want to minimize the number of access to hard drive by using the locality principle!!!

# We want to store large sets of indexes

## First

We assume that the set is so voluminous that only a small part can be kept in main memory!!!

## Thus

We want to minimize the number of access to hard drive by using the locality principle!!!

## Application: Minimizing disk access when looking for indexes in databases

Each node is stored as a page

Page size determines  $t$ . Since  $t$  is usually large, this implies a large branching factor, so height is small.

Example with  $t = 1000$ : we have 1000 (key elements) per node

## Application: Minimizing disk access when looking for indexes in databases

Each node is stored as a page

Page size determines  $t$ . Since  $t$  is usually large, this implies a large branching factor, so height is small.

Example with  $t = 1001$ , we have 1000 (key, elements) per node

# Application: Minimizing disk access when looking for indexes in databases

Example with  $(2t - 1) + 1 = 1001$ , we have 1000 (key, elements) per node

# Application: Minimizing disk access when looking for indexes in databases

## The example above

- It can hold over one billion keys.
  - ▶ the height is only 2 (Assuming root at height 0), so we can find any key with only two disk accesses (Compared to red-black trees, where the branching factor is 2).
  - ▶ Then, disk accesses are minimal!!!

# Application: Minimizing disk access when looking for indexes in databases

## The example above

- It can hold over one billion keys.
  - ▶ the **height is only 2** (Assuming root at height 0), so we can find any key with only two disk accesses (Compared to red-black trees, where the branching factor is 2).
  - ▶ Then, disk accesses are minimal!!!

# Height of a B-Tree

## Theorem 18.1

Let  $n$  be the number of keys in  $T$ ,  $n \geq 1$ ,  $t \geq 2$ , and  $h$  be the height of  $T$ . Then  $h \leq \log_t \frac{n+1}{2}$

### Proof

- The root of a B-tree  $T$  contains at least one key, and all other nodes contain at least  $t - 1$  keys.

# Height of a B-Tree

## Theorem 18.1

Let  $n$  be the number of keys in  $T$ ,  $n \geq 1$ ,  $t \geq 2$ , and  $h$  be the height of  $T$ . Then  $h \leq \log_t \frac{n+1}{2}$

## Proof

- The root of a B-tree  $T$  contains at least one key, and all other nodes contain at least  $t - 1$  keys.
- Thus,  $T$ , whose height is  $h$ ,
  - ▶ It has at least 2 nodes at depth 1.
  - ▶ At least  $2t$  nodes at depth 2.
  - ▶ At least  $2t^2$  nodes at depth 3.
  - ▶ Then, depth  $h$  has at least  $2t^{h-1}$  nodes.

# Height of a B-Tree

## Theorem 18.1

Let  $n$  be the number of keys in  $T$ ,  $n \geq 1$ ,  $t \geq 2$ , and  $h$  be the height of  $T$ . Then  $h \leq \log_t \frac{n+1}{2}$

## Proof

- The root of a B-tree  $T$  contains at least one key, and all other nodes contain at least  $t - 1$  keys.
- Thus,  $T$ , whose height is  $h$ ,
  - ▶ It has at least 2 nodes at depth 1.
  - ▶ At least  $2t$  nodes at depth 2.
  - ▶ At least  $2t^2$  nodes at depth 3.
  - ▶ Then, depth  $h$  has at least  $2t^{h-1}$  nodes.

# Height of a B-Tree

## Theorem 18.1

Let  $n$  be the number of keys in  $T$ ,  $n \geq 1$ ,  $t \geq 2$ , and  $h$  be the height of  $T$ . Then  $h \leq \log_t \frac{n+1}{2}$

## Proof

- The root of a B-tree  $T$  contains at least one key, and all other nodes contain at least  $t - 1$  keys.
- Thus,  $T$ , whose height is  $h$ ,
  - ▶ It has at least 2 nodes at depth 1.
  - ▶ At least  $2t$  nodes at depth 2.
  - ▶ At least  $2t^2$  nodes at depth 3.
  - ▶ Then, depth  $h$  has at least  $2t^{h-1}$  nodes.

# Height of a B-Tree

## Theorem 18.1

Let  $n$  be the number of keys in  $T$ ,  $n \geq 1$ ,  $t \geq 2$ , and  $h$  be the height of  $T$ . Then  $h \leq \log_t \frac{n+1}{2}$

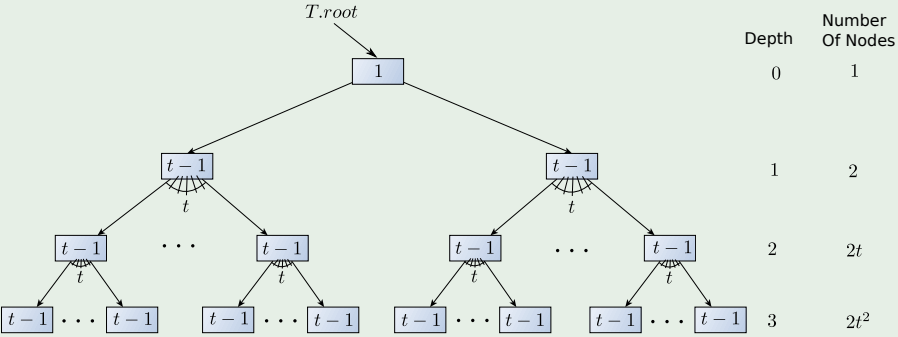

## Proof

- The root of a B-tree  $T$  contains at least one key, and all other nodes contain at least  $t - 1$  keys.
- Thus,  $T$ , whose height is  $h$ ,
  - ▶ It has at least 2 nodes at depth 1.
  - ▶ At least  $2t$  nodes at depth 2.
  - ▶ At least  $2t^2$  nodes at depth 3.
  - ▶ Then, depth  $h$  has at least  $2t^{h-1}$  nodes.

# For example

We have the following

# Height of a B-Tree

## We have at least

- ① Depth 0 - One key
- ② Depth 1 -  $2t^0(t - 1)$
- ③ Depth 2 -  $2t^1(t - 1)$
- ④ Depth 3 -  $2t^2(t - 1)$
- ⑤ ...

# Height of a B-Tree

## We have at least

- 1 Depth 0 - One key
- 2 Depth 1 -  $2t^0(t - 1)$
- 3 Depth 2 -  $2t^1(t - 1)$
- 4 Depth 3 -  $2t^2(t - 1)$
- 5 ...

Thus

$$n \geq 1 + (t - 1) \sum_{i=1}^h 2t^{i-1} \quad (2)$$

# Height of a B-Tree

## We have at least

- 1 Depth 0 - One key
- 2 Depth 1 -  $2t^0(t - 1)$
- 3 Depth 2 -  $2t^1(t - 1)$
- 4 Depth 3 -  $2t^2(t - 1)$

Thus

$$n \geq 1 + (t - 1) \sum_{i=1}^h 2t^{i-1} \quad (2)$$

# Height of a B-Tree

## We have at least

- 1 Depth 0 - One key
- 2 Depth 1 -  $2t^0(t - 1)$
- 3 Depth 2 -  $2t^1(t - 1)$
- 4 Depth 3 -  $2t^2(t - 1)$
- 5 ...

$$n \geq 1 + (t - 1) \sum_{i=1}^h 2t^{i-1} \quad (2)$$

# Height of a B-Tree

## We have at least

- 1 Depth 0 - One key
- 2 Depth 1 -  $2t^0(t - 1)$
- 3 Depth 2 -  $2t^1(t - 1)$
- 4 Depth 3 -  $2t^2(t - 1)$
- 5 ...

## Thus

$$n \geq 1 + (t - 1) \sum_{i=1}^h 2t^{i-1} \quad (2)$$

# Height of a B-Tree

Finally

$$n \geq 1 + 2(t - 1) \left( \frac{t^h - 1}{t - 1} \right) = 2t^h - 1 \quad (3)$$

# Height of a B-Tree

Finally

$$n \geq 1 + 2(t - 1) \left( \frac{t^h - 1}{t - 1} \right) = 2t^h - 1 \quad (3)$$

Therefore

$$t^h \leq \frac{n + 1}{2} \quad (4)$$

# Height of a B-Tree

Finally

$$h \leq \log_t \frac{n+1}{2} \quad (5)$$

## Using **recursion** to make the search easier

So, we use line 1 to 5

① Move to the key  $x.key[i]$  such that  $k \leq x.key[i]$

② To return the value if stored at the node by the sorted keys!!!

## Using **recursion** to make the search easier

So, we use line 1 to 5

- 1 Move to the key  $x.key[i]$  such that  $k \leq x.key[i]$
- 2 To return the value if stored at the node by the sorted keys!!!

If the node is a leaf

Return NIL == "That key is not in the B-Tree"

## Using **recursion** to make the search easier

So, we use line 1 to 5

- 1 Move to the key  $x.key[i]$  such that  $k \leq x.key[i]$
- 2 To return the value if stored at the node by the sorted keys!!!

If the node is a leaf

Return NIL == “That key is not in the B-Tree”

The key could be in the next level

Then, Disk-Read( $x.c[i]$ ) and call the recursion in the children node already in memory.

## Using **recursion** to make the search easier

So, we use line 1 to 5

- 1 Move to the key  $x.key[i]$  such that  $k \leq x.key[i]$
- 2 To return the value if stored at the node by the sorted keys!!!

If the node is a leaf

Return NIL == “That key is not in the B-Tree”

The key could be in the next level

Then, Disk-Read( $x.c[i]$ ) and call the recursion in the children node already in memory.

# Search operation

## Note

$Search(root[t], k)$  **returns**  $(x, i)$  **or**  $NIL$  **if no such key.**

# Cost of Search

## Worst Cost

- $O(h) = O(\log_t n)$  disk reads when going through the entire tree.
- $x.n < 2t \Rightarrow O(t)$  for searching the key at each node
- Finally, we have that  $O(th) = O(t \log_t n)$  CPU time.

# Cost of Search

## Worst Cost

# Insertion

## Something Notable

Here is where the things become interesting!!!

- Insertions can only be done in non-full nodes.
- The holding data structures for keys and pointers are arrays!!!

# Insertion

## Something Notable

Here is where the things become interesting!!!

- Insertions can only be done in non-full nodes.
  - The holding data structures for keys and pointers are arrays!!!

What?

This means that if a node has  $2t - 1$  keys, something needs to be done in order to make space in the node.

# Insertion

## Something Notable

Here is where the things become interesting!!!

- Insertions can only be done in non-full nodes.
- The holding data structures for keys and pointers are arrays!!!

## What?

This means that if a node has  $2l - 1$  keys, something needs to be done in order to make space in the node.

## Process

- 1 Split the node around the median key.
- 2 You finish with two nodes of size  $l - 1$  and the median key  $y$ .
- 3 Promote the median key to the father node to identify the new ranges.
- 4 If the father is full recursively split the father to make room.

# Important!!!

We always insert at...

**THE LEAF LEVEL!!!**

Therefore

What if the leaf child becomes full?

# Important!!!

We always insert at...

THE LEAF LEVEL!!!

Therefore

What if the leaf child becomes full?

# Splitting

## Splitting

Applied to a full child of a non-full parent when full  $\equiv 2t - 1$  keys.

Example with  $t = 1$

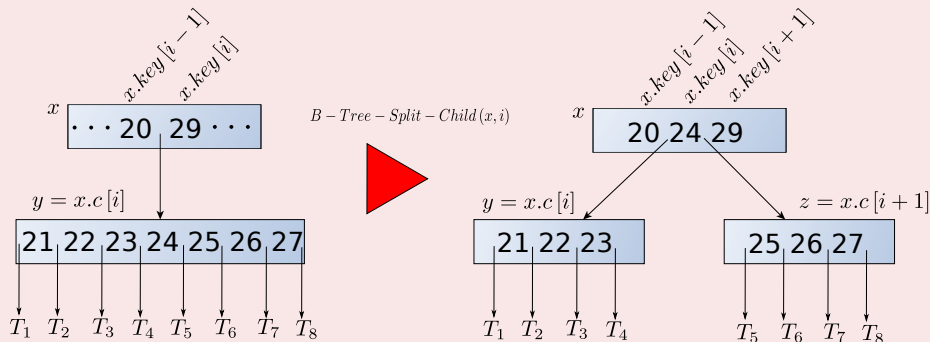

# Splitting

## Splitting

Applied to a full child of a non-full parent when full  $\equiv 2t - 1$  keys.

## Example with $t = 4$

# Split-Child

## Algorithm

B-Tree-Split-Child( $x, i$ )

1.  $z = \text{Allocate-Node}()$
2.  $y = x.c_i$
3.  $z.\text{leaf} = y.\text{leaf}$
4.  $z.n = t - 1$
5. **for**  $j = 1$  **and**  $t - 1$
6.      $z.\text{key}[j] = y.\text{key}[j + t]$
7. **if not**  $y.\text{leaf}$
8.     **for**  $j = 1$  **to**  $t$
9.          $z.c[j] = y.c[j + t]$
10.  $y.n = t - 1$
11. **for**  $j = x.n + 1$  **downto**  $i + 1$
12.      $x.c[j + 1] = x.c[j]$
13.  $x.c[i + 1] = z$
14. **for**  $j = x.n$  **downto**  $i$
15.      $x.\text{key}[j + 1] = x.\text{key}[j]$
16.  $x.\text{key}[i] = y.\text{key}[t]$
17.  $x.n = x.n + 1$
18. **Disk-Write**( $y$ )
19. **Disk-Write**( $z$ )
20. **Disk-Write**( $x$ )

# Explanation

## First

- The code works as follow:
  - ▶ the element  $y$  has  $2t$  children ( $2t - 1$  keys) but is reduced to  $t$  children.
  - ▶ For this, the new node  $z$  takes the  $t$  largest children from  $y$ , and  $z$  becomes a new child of  $x$ .

# Explanation

## First

- The code works as follow:
  - ▶ the element  $y$  has  $2t$  children ( $2t - 1$  keys) but is reduced to  $t$  children.
  - ▶ For this, the new node  $z$  takes the  $t$  largest children from  $y$ , and  $z$  becomes a new child of  $x$ .

# Explanation

## First

- The code works as follow:
  - ▶ the element  $y$  has  $2t$  children ( $2t - 1$  keys) but is reduced to  $t$  children.
  - ▶ For this, the new node  $z$  takes the  $t$  largest children from  $y$ , and  $z$  becomes a new child of  $x$ .

# Detailed Explanation

## First

Lines 1-4 creates node  $z$

1.  $z = \mathbf{Allocate-Node}()$
2.  $y = x.c_i$
3.  $z.leaf = y.leaf$
4.  $z.n = t - 1$

Lines 1-4

# Detailed Explanation

## First

Lines 5-6 copies the keys from position  $j + 1$  in the  $y$  node to position  $j$  in node  $z$ :

5. **for**  $j = 1$  and  $t - 1$
6.  $z.key[j] = y.key[j + t]$

Lines 5-6

# Detailed Explanation

## First

Lines 5-6 copies the keys from position  $j + 1$  in the  $y$  node to position  $j$  in node  $z$ :

5. **for**  $j = 1$  and  $t - 1$
6.  $z.key[j] = y.key[j + t]$

Lines 5-6

# Detailed Explanation

Then

Lines 7-8 are used to copy the children if you are not a leaf

7. **if not**  $y.\text{leaf}$

8.           **for**  $j = 1$  **to**  $t$

9.                    $z.c[j] = y.c[j + t]$

# Detailed Explanation

Then

Lines 7-8 are used to copy the children if you are not a leaf

7. **if not**  $y.\text{leaf}$

8.           **for**  $j = 1$  **to**  $t$

9.                    $z.c[j] = y.c[j + t]$

## Detailed Explanation

Then

Lines 7-8 are used to copy the children if you are not a leaf

7. **if not**  $y$ .leaf

8.           **for**  $j = 1$  **to**  $t$

9.                    $z.c[j] = y.c[j + t]$

## Detailed Explanation

Then

Line 10 adjust the count for  $y$ .

$$10. \quad y.n = t - 1$$

# Detailed Explanation

Then

Line 11-13 make space to the pointer for the  $z$  node

11. **for**  $j = x.n + 1$  **downto**  $i + 1$
12.  $x.c[j + 1] = x.c[j]$
13.  $x.c[i + 1] = z$

# Detailed Explanation

Then

Line 11-13 make space to the pointer for the  $z$  node

11. **for**  $j = x.n + 1$  **downto**  $i + 1$
12.  $x.c[j + 1] = x.c[j]$
13.  $x.c[i + 1] = z$

# Detailed Explanation

Then

Line 14-15 make space to key from the  $z$  node to the node  $x$

14. **for**  $j = x.n$  **downto**  $i$

15.        $x.key[j + 1] = x.key[j]$

# Detailed Explanation

Then

Line 16-17 copy the key to the correct place and increase the counter of  $x$

$$16. x.key[i] = y.key[t]$$

$$17. x.n = x.n + 1$$

# Detailed Explanation

Then

Line 18-20 Write everything to the hard drive

18. **Disk-Write**( $y$ )

19. **Disk-Write**( $z$ )

20. **Disk-Write**( $x$ )

# Cost of Split-Child

## Complexity

- $\Theta(t)$  CPU time the for loop to go through the keys
- $O(1)$  disk writes.

# Insert

# Insert-Full

## Note

First, modify tree (if necessary) to create room for new key. Then, call Insert-Nonfull()

## Example

# Insert-Full

## Note

First, modify tree (if necessary) to create room for new key. Then, call Insert-Nonfull()

## Example

# Insert-Nonfull

## Algorithm

B-Tree-Insert-Nonfull( $x, k$ )

1.  $i = x.n$
2. **if**  $x.leaf$
3.     **while**  $i \geq 1$  **and**  $k < x.key[i]$
4.          $x.key[i + 1] = x.key[i]$
5.          $i = i - 1$
6.      $x.key[i + 1] = k$
7.      $x.n = x.n + 1$
8.     **Disk-Write**( $x$ )
9. **else while**  $i \geq 1$  **and**  $k < x.key[i]$
10.          $i = i - 1$
11.          $i = i + 1$
12.         **Disk-Read**( $x.c[i]$ )
13.         **if**  $x.c[i].n == 2t - 1$
14.             **B-Tree-Split-Child**( $x, i$ )
15.             **if**  $k > x.key[i]$
16.                  $i = i + 1$
17.         **B-Tree-Insert-Nonfull**( $x.c[i], k$ )

# Explanation

## Line 1

it gets the rightmost key of the B-Tree

1.  $i = x.n$

2.  $x.key[i] = MINVAL$

We make space on the key array because we have space for it.

3.       while  $i \geq 1$  and  $k < x.key[i]$

4.              $x.key[i+1] = x.key[i]$

5.              $i = i - 1$

# Explanation

## Line 1

it gets the rightmost key of the B-Tree

1.  $i = x.n$

## if $x.leaf == TRUE$

We make space on the key array because we have space for it.

3.       **while**  $i \geq 1$  **and**  $k < x.key[i]$

4.                $x.key[i + 1] = x.key[i]$

5.                $i = i - 1$

## Explanation

Insert the key with the payload at the correct position and increase the counter of  $x$

$$6. \quad x.key[i + 1] = k$$

$$7. \quad x.n = x.n + 1$$

Write everything to the disk

$$8. \quad \text{Disk-Write}(x)$$

## Explanation

Insert the key with the payload at the correct position and increase the counter of  $x$

$$6. \quad x.key[i + 1] = k$$

$$7. \quad x.n = x.n + 1$$

Write everything to the disk

$$8. \quad \text{Disk-Write}(x)$$

# Explanation

```
if  $x.leaf! = TRUE$ 
```

Get into the correct child and bring it from the hard drive

9. **else while**  $i \geq 1$  **and**  $k < x.key[i]$
10.                    $i = i - 1$
11.            $i = i + 1$
12.       **Disk-Read**( $x.c[i]$ )

if the child  $x.c[i]$  is full split it

13.           if  $x.c[i].n == 2t - 1$
14.                **B-Tree-Split-Child**( $x, i$ )

## Explanation

if  $x.leaf! = TRUE$

Get into the correct child and bring it from the hard drive

9. **else while**  $i \geq 1$  **and**  $k < x.key[i]$
10.                     $i = i - 1$
11.             $i = i + 1$
12.        **Disk-Read**( $x.c[i]$ )

if the child  $x.c[i]$  is full split it

13.        **if**  $x.c[i].n == 2t - 1$
14.                **B-Tree-Split-Child**( $x, i$ )

# Explanation

Now we need to decide

if  $k == x.key[i]$

- Then, we take the left child of  $x.key[i]$

if not,

- we take the right child of  $x.key[i]$

15.                   if  $k > x.key[i]$

16.                     $i = i + 1$

# Explanation

## Now we need to decide

if  $k == x.key[i]$

- Then, we take the left child of  $x.key[i]$

if not,

- we take the right child of  $x.key[i]$

15.                   if  $k > x.key[i]$

16.                    $i = i + 1$

After that, we insert in a non-full element

17.           B-Tree-Insert-Nonfull( $x.c[i], k$ )

# Explanation

## Now we need to decide

if  $k == x.key[i]$

- Then, we take the left child of  $x.key[i]$

If not,

- we take the right child of  $x.key[i]$

15.                   if  $k > x.key[i]$

16.                    $i = i + 1$

After that, we insert in a non-full element

17.           B-Tree-Insert-Nonfull( $x.c[i], k$ )

# Explanation

## Now we need to decide

if  $k == x.key[i]$

- Then, we take the left child of  $x.key[i]$

If not,

- we take the right child of  $x.key[i]$

15.                   if  $k > x.key[i]$

16.                    $i = i + 1$

After that, we insert in a non-full element

17.                   B-Tree-Insert-Nonfull( $x.c[i]$ ,  $k$ )

## Explanation

### Now we need to decide

if  $k == x.key[i]$

- Then, we take the left child of  $x.key[i]$

If not,

- we take the right child of  $x.key[i]$

15.                    **if**  $k > x.key[i]$

16.                     $i = i + 1$

### After that, we insert in a non-full element

17.                    **B-Tree-Insert-Nonfull**( $x.c[i], k$ )

# Cost of Insertion

## Worst case

- $\Theta(\log_t n)$  disk writes.
- $\Theta(t \log_t n)$  CPU time.

## Example of Constructing a B-Tree by Insertion

### Proceed as follows

Suppose we start with an empty B-Tree and keys arrive in the following order:

- 1, 12, 8, 2, 25, 6, 14, 28, 19, 20, 17, 7, 52, 16, 48, 60, 68, 3, 26, 29, 53, 55, 24, 23, 22, 11.

## Example of Constructing a B-Tree by Insertion

### Proceed as follows

Suppose we start with an empty B-Tree and keys arrive in the following order:

- 1, 12, 8, 2, 25, 6, 14, 28, 19, 20, 17, 7, 52, 16, 48, 60, 68, 3, 26, 29, 53, 55, 24, 23, 22, 11.

### Something Notable

- We want to build a B-Tree with at most 5 keys. Thus:

$$2t - 1 = 5$$

$$2t = 6$$

$$t = 3$$

## Example of Constructing a B-Tree by Insertion

### Proceed as follows

Suppose we start with an empty B-Tree and keys arrive in the following order:

- 1, 12, 8, 2, 25, 6, 14, 28, 19, 20, 17, 7, 52, 16, 48, 60, 68, 3, 26, 29, 53, 55, 24, 23, 22, 11.

### Something Notable

- We want to build a B-Tree with at most 5 keys. Thus:

$$2t - 1 = 5$$

$$2t = 6$$

$$t = 3$$

## Example of Constructing a B-Tree by Insertion

### Proceed as follows

Suppose we start with an empty B-Tree and keys arrive in the following order:

- 1, 12, 8, 2, 25, 6, 14, 28, 19, 20, 17, 7, 52, 16, 48, 60, 68, 3, 26, 29, 53, 55, 24, 23, 22, 11.

### Something Notable

- We want to build a B-Tree with at most 5 keys. Thus:

$$2t - 1 = 5$$

$$2t = 6$$

$$t = 3$$

# First

We insert the first 5 elements in the root node

*T.root*

1 2 8 12 25

# Constructing a B-Tree

Then, we want to insert 6 and for this we split promoting 8

# Constructing a B-Tree

Then, we want to insert 6 and for this we split promoting 8

# Constructing a B-Tree

6, 14, 28, 19 get added to the leaf nodes

# Constructing a B-Tree

Add 20, Split necessary by promoting 19

# Constructing a B-Tree

Add 20 to the leaf node

# Constructing a B-Tree

Add 17, 7, 52, 16, 48 to the leaf nodes

## Constructing a B-Tree

Add 60 to a leaf node, it is necessary to split by promoting 28 to the root

# Constructing a B-Tree

Add 60

# Constructing a B-Tree

Add 68, 3, 26, 27, 53 to the leaf nodes

# Constructing a B-Tree

Add 68, 3, 26, 27, 53 to the leaf nodes

# Constructing a B-Tree

Add 55 by splitting a leaf node and promoting 54

# Constructing a B-Tree

Add 55 to the leaf

# Constructing a B-Tree

Add 24 to the leaf

# Constructing a B-Tree

Add 22 by splitting a leaf node and promoting 25

# Constructing a B-Tree

Add 11 to the leaf node by adding a empty root node

# Constructing a B-Tree

Split the old root by promoting 25

# Constructing a B-Tree

Add 11 to the leaf

# Deletion

## Main idea

Recursively descend the tree.

## Ensure

Ensure any non-root node  $x$  that is considered for deletion has at least  $t$  keys.

## Note that

May have to move a key down from parent.

# Deletion

## Main idea

Recursively descend the tree.

## Ensure

Ensure any non-root node  $x$  that is considered for deletion has at least  $t$  keys.

Note that

May have to move a key down from parent.

# Deletion

## Main idea

Recursively descend the tree.

## Ensure

Ensure any non-root node  $x$  that is considered for deletion has at least  $t$  keys.

## Note that

May have to move a key down from parent.

## Deletion Cases

Case 0: You delete the only key at the root  $\approx$  Empty root

Then, you make root's only child the new root:

Case 1:  $k$  in  $x$  and  $x.l \neq \perp \wedge x.r \neq \perp$ , then delete  $k$  from  $x$

# Deletion Cases

Case 0: You delete the only key at the root  $\approx$  Empty root

Then, you make root's only child the new root:

Case 1:  $k$  in  $x$  and  $x.leaf == TRUE$ , then delete  $k$  from  $x$ .

# Deletion Cases

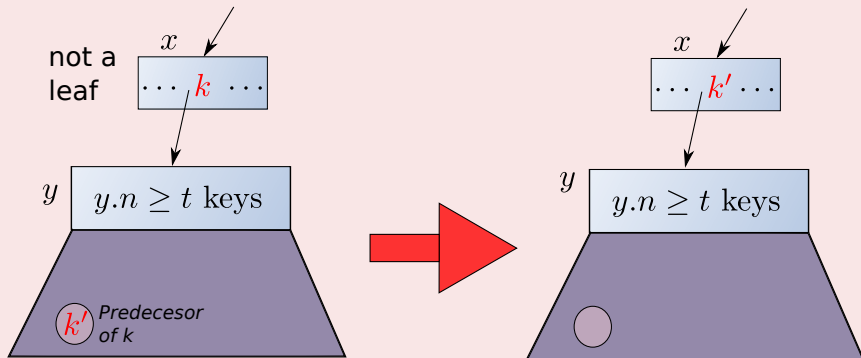

## Case 2: $k$ in $x$ , $x$ internal

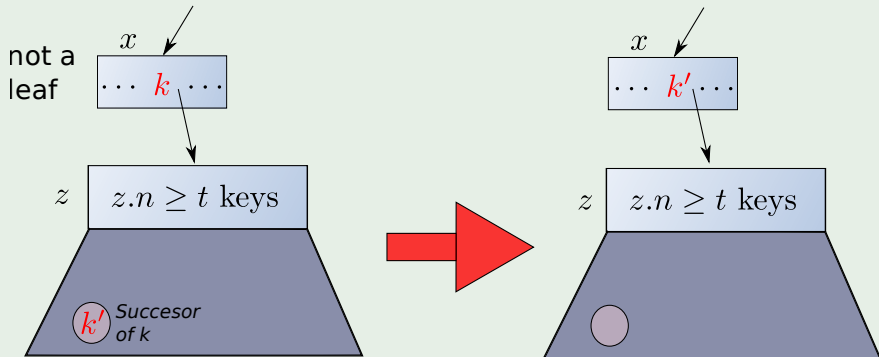

## Deletion Cases

Subcase A:  $y$  has at least  $t$  keys; find predecessor  $k'$  of  $k$  in subtree rooted at  $y$ , recursively delete  $k'$ , replace  $k$  by  $k'$  in  $x$ .

## Deletion Cases

Subcase B:  $z$  has at least  $t$  keys; find successor  $k'$  in subtree rooted at  $z$ , recursively delete  $k'$ , replace  $k$  by  $k'$  in  $x$ .

## Deletion Cases

Subcase C:  $y$  and  $z$  both have  $t - 1$  keys; merge  $k$  and  $z$  into  $y$ , free  $z$ , recursively delete  $k$  from  $y$ .

# Deletion cases

## Case 3

- If the key  $k$  is not present in internal node  $x$ , determine the root  $x.c_i$  of the appropriate subtree that must contain  $k$ , if  $k$  is in the tree at all.
- If  $x.c_i$  has only  $t - 1$  keys, execute step 3a or 3b as necessary to guarantee that we descend to a node containing at least  $t$  keys.
- Then finish by recursing on the appropriate child of  $x$ .

# Deletion cases

## Case 3

- If the key  $k$  is not present in internal node  $x$ , determine the root  $x.c_i$  of the appropriate subtree that must contain  $k$ , if  $k$  is in the tree at all.
- If  $x.c_i$  has only  $t - 1$  keys, execute step 3a or 3b as necessary to guarantee that we descend to a node containing at least  $t$  keys.
- Then finish by recursing on the appropriate child of  $x$ .

# Deletion cases

## Case 3

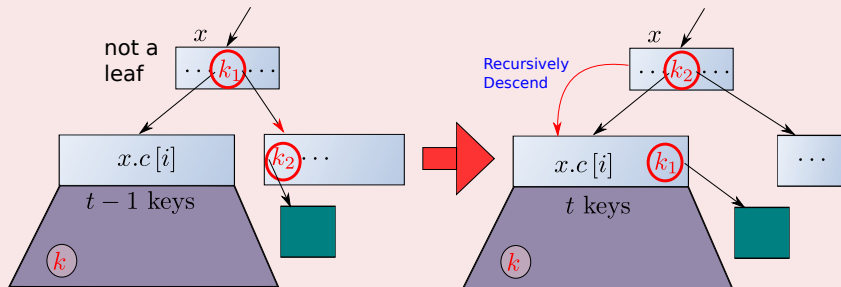

- If the key  $k$  is not present in internal node  $x$ , determine the root  $x.c_i$  of the appropriate subtree that must contain  $k$ , if  $k$  is in the tree at all.
- If  $x.c_i$  has only  $t - 1$  keys, execute step 3a or 3b as necessary to guarantee that we descend to a node containing at least  $t$  keys.
- Then finish by recursing on the appropriate child of  $x$ .

## Case 3.A

### Subcase A

If  $x.c_i$  has only  $t - 1$  keys but has an immediate sibling with at least  $t$  keys, give  $x.c_i$  an extra key by moving a key from  $x$  down into  $x.c_i$ , moving a key from  $x.c_i$ 's immediate left or right sibling up into  $x$ , and moving the appropriate child pointer from the sibling into  $x.c_i$ .

## Case 3.B

### Subcase B

If  $x.c_i$  and both of  $x.c_i$ 's immediate siblings have  $t - 1$  keys, merge  $x.c_i$  with one sibling, which involves moving a key from  $x$  down into the new merged node to become the median key for that node.

# Delete Example

## Delete 14 - Case 3.B

# Delete Example

Delete 14 - move 25 down from the root and join the children nodes

# Delete Example

Delete 14

# Delete Example

## Case 0

# Delete Example

## Delete 28 - Case 2.C

# Delete Example

Join the left and right children of 28 and move it down

# Delete Example

## Recursively Delete 28

# Delete Example

## Delete 25 - Case 2.B

# Delete Example

Move 26 to the position of 25

# Delete Example

Move 26 to the position of 25

# Reasons for using B-Trees

## Justification

When searching tables held on disc, the cost of each disc transfer is high, but does not depend much on the amount of data transferred, especially if consecutive items are transferred.

# Reasons for using B-Trees

## Justification

When searching tables held on disc, the cost of each disc transfer is high, but does not depend much on the amount of data transferred, especially if consecutive items are transferred.

## Example

- If we use a B-Tree of order 101, say, we can transfer each node in one disc read operation.
- A B-Tree of order 101 and height 3 can hold  $101^4 - 1$  items (approximately 100 million) and any item can be accessed with 3 disc reads (assuming we hold the root in memory).

# Reasons for using B-Trees

## Justification

When searching tables held on disc, the cost of each disc transfer is high, but does not depend much on the amount of data transferred, especially if consecutive items are transferred.

# Comparing trees

## Binary trees

- They can become unbalanced and lose their good time complexity (big O).
- AVL trees are strict binary trees that overcome the balance problem.
- Heaps remain balanced, but only prioritize (not order) the keys.

# Comparing trees

## Binary trees

- They can become unbalanced and lose their good time complexity (big O).
- AVL trees are strict binary trees that overcome the balance problem.
- Heaps remain balanced, but only prioritize (not order) the keys.

## Multitway trees

- B-Trees can be m-way, they have any even number of children.
- The 2-3 (or 3 way) approximates a permanently balanced binary tree.

# Extending the B-Tree Structure: B+ Trees

## B+ Tree

A B+ Tree is like a B-tree except that the interior and leaf nodes have a different structure.

### Overall

A B+ tree can be viewed as a B-tree in which each node contains only keys and pointers to the children.

### Finally

At leaves level you have the real data items(They could be pointers to specific data).

### Note

This allows to pack more information in each node.

# Extending the B-Tree Structure: B+ Trees

## B+ Tree

A B+ Tree is like a B-tree except that the interior and leaf nodes have a different structure.

## Actually

A B+ tree can be viewed as a B-tree in which each node contains only keys and pointers to the children.

## Finally

At leaves level you have the real data items(They could be pointers to specific data).

## Note

This allows to pack more information in each node.
